Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

Philip Bille

Dictionaries

- Dictionary problem. Maintain a set $S \subseteq U = \{0, \, ..., \, u\text{-}1\}$ supporting
 - + lookup(x): return true if $x \in S$ and false otherwise.
 - insert(x): set $S = S \cup \{x\}$
 - delete(x): set S = S {x}
- Think universe size $u=2^{64}$ or $2^{32}\,and\,|S|\ll u.$
- Satellite information. We may also have associated satellite information for each key.
- Goal. A compact data structure (linear space) with fast operations (constant time).

Dictionaries

Applications.

- Maintain a dictionary (!)
- Key component in many data structures and algorithms. (Examples in exercises and later lectures).

Hashing

Dictionaries

- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

Dictionaries

- Which solutions do we know?
 - · Direct addressing (bitvector)
 - Linked lists.
 - Binary search trees (balanced)
 - Chained hashing

Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

Chained Hashing

- Simplifying assumption. $|S| \le N$ at all times and we can use space O(N).
- · Chained hashing [Dumey 1956].
 - Pick some crazy, chaotic, random function h (the hash function) mapping U to {0, ..., N-1}.
 - Initialize an array A[0, ..., N-1].
 - A[i] stores a linked list containing the keys in S whose hash value is i.

Chained Hashing

- Operations. How can we support lookup, insert, and delete?
 - Lookup(x): Compute h(x). Scan through list for h(x). Return true if x is in list and false otherwise.
 - Insert(x): Compute h(x). Scan through list for h(x). If x is in list do nothing. Otherwise, add x to the front of list.
 - Delete(x): Compute h(x). Scan through list for h(x). If x is in list remove it. Otherwise, do nothing.
- Time. O(1 + length of linked list for h(x))

Chained Hashing

- Hash functions. A crazy, chaotic hash function (like $h(x) = x \mod 10$) sounds good, but there is a big problem.
 - For any fixed choice of h, we can find a set whose elements all map to the same slot.
 - \Rightarrow We end up with a single linked list.
 - How can we overcome this?
- · Use randomness.
 - · Assume the input set is random.
 - Choose the hash function at random.

Chained Hashing

- · Chained hashing for random hash functions.
 - Assumption 1. h: U \rightarrow {0, ..., N-1} is chosen uniformly at random from the set of all functions from U to {0, ..., N-1}.
 - Assumption 2. h can be evaluated in constant time.
- What is the expected time for an operation OP(x), where OP = {lookup, insert, delete}?

Chained Hashing

$$\begin{split} \text{Time for OP}(x) &= O\left(1 + E\left[\text{length of linked list for } h(x)\right]\right) \\ &= O\left(1 + E\left[\left|\left\{y \in S \mid h(y) = h(x)\right\}\right|\right]\right) \\ &= O\left(1 + E\left[\sum_{y \in S} \left\{\begin{matrix} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{matrix}\right]\right) \\ &= O\left(1 + \sum_{y \in S} E\left[\left\{\begin{matrix} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{matrix}\right]\right) \\ &= O(1 + \sum_{y \in S} \Pr[h(x) = h(y)]) \\ &= O(1 + 1 + \sum_{y \in S \setminus \{x\}} \Pr[h(x) = h(y)]) \\ &= O(1 + 1 + \sum_{y \in S \setminus \{x\}} 1/N) \\ &= O(1 + 1 + N(1/N)) = O(1) \end{split}$$

Chained Hashing

- Theorem. With a random hash function (under assumptions 1 + 2) we can solve the dictionary problem in
 - O(N) space.
 - O(1) expected time per operation (lookup, insert, delete).
- Expectation is over the choice of hash function.
- · Independent of the input set.

Random Hash Functions

- Random hash functions. Can we efficiently compute and store a random function?
 - We need u log N bits to store an arbitrary function from {0,..., u-1} to {0,..., N-1} (specify for each element x in U the value h(x)).
 - We need a lot of random bits to generate the function.
 - We need a lot of time to generate the function.

Random Hash Functions

Time

- Do we need a truly random hash function?
- · When did we use the fact that h was random in our analysis?

$$\begin{split} &\text{for OP}(x) = O\left(1 + E\left[\text{length of linked list for } h(x)\right]\right) \\ &= O\left(1 + E\left[|\{y \in S \mid h(y) = h(x)\}|]\right) \\ &= O\left(1 + E\left[\sum_{y \in S} \left\{\begin{matrix} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{matrix}\right]\right) \\ &= O\left(1 + \sum_{y \in S} E\left[\left\{\begin{matrix} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{matrix}\right]\right) \\ &= O(1 + \sum_{y \in S} \Pr[h(x) = h(y)]) \\ &= O(1 + 1 + \sum_{y \in S \setminus \{x\}} \Pr[h(x) = h(y)]) \\ &= O(1 + 1 + \sum_{y \in S \setminus \{x\}} 1/N) \quad \text{For all } x \neq y, \ \Pr[h(x) = h(y)] \leq 1/N \\ &= O(1 + 1 + N(1/N)) = O(1) \end{split}$$

Random Hash Functions

- We do not need a truly random hash function!
- We only need: For all $x \neq y$, $Pr[h(x) = h(y)] \le 1/N$
- Captured in definition of universal hashing.

Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

Universal Hashing

- Positional number systems. For integers x and p, the base-p representation of x is x written in base p.
- Example.
 - $(10)_{10} = (1010)_2 (1 \cdot 2^3 + 0 \cdot 2^2 + 1 \cdot 2^1 + 0 \cdot 2^0)$
 - $(107)_{10} = (212)_7 (2 \cdot 7^2 + 1 \cdot 7^1 + 2 \cdot 7^0)$

Universal Hashing

- Universel hashing [Carter and Wegman 1979].
 - Let H be a set of functions mapping U to {0, ..., N-1}.
 - + H is universal if for any $x{\neq}y$ in U and h chosen uniformly at random in H,

 $\Pr[h(x) = h(y)] \le 1/N$

- · Universal hashing and chaining.
 - · If we can find family of universal hash functions such that
 - we can store it in small space
 - we can evaluate it in constant time
 - \Rightarrow efficient chained hashing without special assumptions.

Universal Hashing

- Hash function. Given a prime $N and <math>a = (a_1a_2...a_r)_p$, define $h_a(x = (x_1x_2...x_r)_p) = a_1x_1 + a_2x_2 + ... + a_rx_r \mod p$
- Example.
- p = 7
- $a = (107)_{10} = (212)_7$
- $x = (214)_{10} = (424)_7$
- $h_a(x) = 2 \cdot 4 + 1 \cdot 2 + 2 \cdot 4 \mod 7 = 18 \mod 7 = 4$
- · Universal family.
 - $\bullet \ H = \{h_a \mid a = (a_1a_2...a_r)_p \in \{0, \, ..., \, p\text{-}1\}^r\}$
 - Choose random hash function from H ~ choose random a.
 - H is universal (next slides).
 - O(1) time evaluation.
 - O(1) space.
 - Fast construction (find suitable prime).

Universal Hashing

- Lemma. Let p be a prime. For any $a \in \{1, ..., p-1\}$ there exists a unique inverse a^{-1} such that $a^{-1} \cdot a \equiv 1 \mod p$. (Z_p is a field)
- Example. p = 7

Universal Hashing

- Lemma. H is universal with O(1) time evaluation and O(1) space.
- Theorem. We can solve the dictionary problem (without special assumptions) in:
 O(N) space.
 - O(1) expected time per operation (lookup, insert, delete).

Other Universal Families

+ For prime $p>0,\,a\in\{1,\,..,\,p\text{-}1\},\,b\in\{0,\,...,\,p\text{-}1\}$

$$\begin{split} h_{a,b}(x) &= (ax+b \bmod p) \bmod N \\ H &= \{h_{a,b} \mid a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\}\} \end{split}$$

• Hash function from k-bit numbers to I-bit numbers. a is an odd k-bit integer.

I most significant bits of the k least significant bits of ax

$$\begin{aligned} h_a(x) &= (ax \bmod 2^k) \gg (k-l) \checkmark \\ H &= \{h_a \mid a \text{ is an odd integer in } \{1, \dots, 2^k - 1\} \} \end{aligned}$$

Hashing

- Dictionaries
- · Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

Static Dictionaries and Perfect Hashing

- Dynamic solution. Use chained hashing with a universal hash function as before \Rightarrow solution with O(N) space and O(1) expected time per lookup.
 - · Can we do better?
- Perfect Hashing. A perfect hash function for S is a collision-free hash function on S.
 - Perfect hash function in O(N) space and O(1) evaluation time \Rightarrow solution with O(N) space and O(1) worst-case lookup time. (Why?)
 - Do perfect hash functions with O(N) space and O(1) evaluation time exist for any set S?

Static Dictionaries and Perfect Hashing

- Static dictionary problem. Given a set $S\subseteq U=\{0,..,u\text{--}1\}$ of size N for preprocessing support the following operation
 - lookup(x): return true if $x \in S$ and false otherwise.
- · As the dictionary problem with no updates (insert and deletes).
- · Set given in advance.

Static Dictionaries and Perfect Hashing

- · Goal. Perfect hashing in linear space and constant worst-case time.
- · Solution in 3 steps.
 - · Solution 1. Collision-free but with too much space.
 - · Solution 2. Many collisions but linear space.
 - Solution 3: FKS scheme [Fredman, Komlós, Szemerédi 1984]. Two-level solution. Combines solution 1 and 2.
 - At level 1 use solution with lots of collisions and linear space.
 - Resolve collisions at level 1 with collision-free solution at level 2.
 - lookup(x): look-up in level 1 to find the correct level 2 dictionary. Lookup in level 2 dictionary.

Static Dictionaries and Perfect Hashing

- Solution 1. Collision-free but with too much space.
- Use a universal hash function to map into an array of size N². What is the expected total number of collisions in the array?

$$\begin{split} E[\#\text{collisions}] &= E\left[\sum_{x,y \in S, x \neq y} \begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases} \right] \\ &= \sum_{x,y \in S, x \neq y} E\left[\begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases} \right] \\ &= \sum_{x,y \in S, x \neq y} \Pr[h(x) = h(y)] = \binom{N}{2} \frac{1}{N^2} \leq \frac{N^2}{2} \cdot \frac{1}{N^2} = 1/2 \\ \text{#distinct pairs} & \text{Universal hashing into N}^2 \text{ range} \end{split}$$

- With probability 1/2 we get perfect hashing function. If not perfect try again.
- \Rightarrow Expected number of trials before we get a perfect hash function is O(1).
- $\bullet \implies$ For a static set S we can support lookups in O(1) worst-case time using O(N²) space.

Static Dictionaries and Perfect Hashing

- · Solution 2. Many collisions but linear space.
- As solution 1 but with array of size N. What is the expected total number of collisions in the array?

Static Dictionaries and Perfect Hashing

• FKS scheme.

- O(N) space and O(N) expected preprocessing time.
- Lookups with two evaluations of a universal hash function.
- Theorem. We can solve the static dictionary problem for a set S of size N in:
 - O(N) space and O(N) expected preprocessing time.
 - O(1) worst-case time per lookup.

· Multilevel data structures.

• FKS is example of multilevel data structure technique. Combine different solutions for same problem to get an improved solution.
