# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

#### **Dictionaries**

- Dictionary problem. Maintain a set S ⊆ U = {0, ..., u-1} supporting
  - lookup(x): return true if  $x \in S$  and false otherwise.
  - insert(x): set  $S = S \cup \{x\}$
  - delete(x): set  $S = S \{x\}$
- Think universe size  $u=2^{64}$  or  $2^{32}$  and  $|S|\ll u$ .
- Satellite information. We may also have associated satellite information for each key.
- Goal. A compact data structure (linear space) with fast operations (constant time).

#### **Dictionaries**

- · Applications.
  - Maintain a dictionary (!)
  - Key component in many data structures and algorithms. (Examples in exercises and later lectures).

# Dictionaries

• Which solutions do we know?

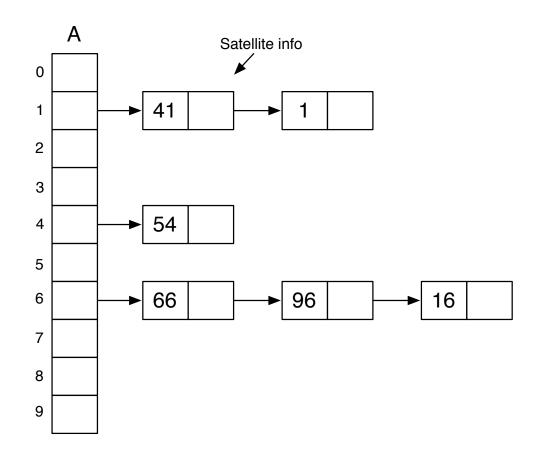

# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

- Simplifying assumption.  $|S| \le N$  at all times and we can use space O(N).
- Chained hashing [Dumey 1956].
  - Pick some crazy, chaotic, random function h (the hash function) mapping U to {0, ..., N-1}.
  - Initialize an array A[0, ..., N-1].
  - A[i] stores a linked list containing the keys in S whose hash value is i.

#### • Example.

- $U = \{0, ..., 99\}$
- $S = \{1, 16, 41, 54, 66, 96\}$
- $h(x) = x \mod 10$

- Operations. How can we support lookup, insert, and delete?
  - Lookup(x): Compute h(x). Scan through list for h(x). Return true if x is in list and false otherwise.
  - Insert(x): Compute h(x). Scan through list for h(x). If x is in list do nothing.
     Otherwise, add x to the front of list.
  - Delete(x): Compute h(x). Scan through list for h(x). If x is in list remove it.
     Otherwise, do nothing.
- Time. O(1 + length of linked list for h(x))

- Hash functions. A crazy, chaotic hash function (like  $h(x) = x \mod 10$ ) sounds good, but there is a big problem.
  - For any fixed choice of h, we can find a set whose elements all map to the same slot.
  - → We end up with a single linked list.
  - How can we overcome this?
- Use randomness.
  - Assume the input set is random.
  - Choose the hash function at random.

- Chained hashing for random hash functions.
  - Assumption 1. h: U → {0, ..., N-1} is chosen uniformly at random from the set of all functions from U to {0, ..., N-1}.
  - Assumption 2. h can be evaluated in constant time.
- What is the expected time for an operation OP(x), where OP = {lookup, insert, delete}?

Time for 
$$\operatorname{OP}(x) = O\left(1 + E\left[\operatorname{length of linked list for } h(x)\right]\right)$$

$$= O\left(1 + E\left[\left|\left\{y \in S \mid h(y) = h(x)\right\}\right|\right]\right)$$

$$= O\left(1 + E\left[\sum_{y \in S} \left\{1 \quad \text{if } h(y) = h(x)\\0 \quad \text{if } h(y) \neq h(x)\right]\right)$$

$$= O\left(1 + \sum_{y \in S} E\left[\left\{1 \quad \text{if } h(y) = h(x)\\0 \quad \text{if } h(y) \neq h(x)\right]\right)$$

$$= O(1 + \sum_{y \in S} \Pr[h(x) = h(y)])$$

$$= O(1 + 1 + \sum_{y \in S \setminus \{x\}} \Pr[h(x) = h(y)])$$

$$= O(1 + 1 + \sum_{y \in S \setminus \{x\}} 1/N)$$

$$= O(1 + 1 + N(1/N)) = O(1)$$
No of which cause collision
$$= O(1 + 1 + N(1/N)) = O(1)$$

- Theorem. With a random hash function (under assumptions 1 + 2) we can solve the dictionary problem in
  - O(N) space.
  - O(1) expected time per operation (lookup, insert, delete).
- Expectation is over the choice of hash function.
- · Independent of the input set.

#### Random Hash Functions

- Random hash functions. Can we efficiently compute and store a random function?
  - We need u log N bits to store an arbitrary function from  $\{0,..., u-1\}$  to  $\{0,..., N-1\}$  (specify for each element x in U the value h(x)).
  - We need a lot of random bits to generate the function.
  - We need a lot of time to generate the function.

#### Random Hash Functions

- Do we need a truly random hash function?
- When did we use the fact that h was random in our analysis?

Time for 
$$OP(x) = O(1 + E [length of linked list for  $h(x)])$   
 $= O(1 + E [|\{y \in S \mid h(y) = h(x)\}|])$   
 $= O\left(1 + E\left[\sum_{y \in S} \begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases}\right]\right)$   
 $= O\left(1 + \sum_{y \in S} E\left[\begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases}\right]\right)$   
 $= O(1 + \sum_{y \in S} \Pr[h(x) = h(y)])$   
 $= O(1 + 1 + \sum_{y \in S \setminus \{x\}} \Pr[h(x) = h(y)])$   
 $= O(1 + 1 + \sum_{y \in S \setminus \{x\}} 1/N)$  For all  $x \neq y$ ,  $\Pr[h(x) = h(y)] \leq 1/N$   
 $= O(1 + 1 + N(1/N)) = O(1)$$$

#### Random Hash Functions

- We do not need a truly random hash function!
- We only need: For all  $x \neq y$ ,  $Pr[h(x) = h(y)] \leq 1/N$
- Captured in definition of universal hashing.

# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

- Universel hashing [Carter and Wegman 1979].
  - Let H be a set of functions mapping U to {0, ..., N-1}.
  - H is universal if for any x≠y in U and h chosen uniformly at random in H,
     Pr[h(x) = h(y)] ≤ 1/N

- Universal hashing and chaining.
  - If we can find family of universal hash functions such that
    - we can store it in small space
    - we can evaluate it in constant time
  - → efficient chained hashing without special assumptions.

- Positional number systems. For integers x and p, the base-p representation of x is x written in base p.
- Example.
  - $(10)_{10} = (1010)_2 (1 \cdot 2^3 + 0 \cdot 2^2 + 1 \cdot 2^1 + 0 \cdot 2^0)$
  - $(107)_{10} = (212)_7 (2 \cdot 7^2 + 1 \cdot 7^1 + 2 \cdot 7^0)$

• Hash function. Given a prime  $N and <math>a = (a_1a_2...a_r)_p$ , define  $h_a(x = (x_1x_2...x_r)_p) = a_1x_1 + a_2x_2 + ... + a_rx_r \bmod p$ 

#### Example.

- p = 7
- $a = (107)_{10} = (212)_7$
- $x = (214)_{10} = (424)_7$
- $h_a(x) = 2 \cdot 4 + 1 \cdot 2 + 2 \cdot 4 \mod 7 = 18 \mod 7 = 4$

#### Universal family.

- $H = \{h_a \mid a = (a_1 a_2 ... a_r)_p \in \{0, ..., p-1\}^r\}$
- Choose random hash function from H ~ choose random a.
- H is universal (next slides).
- O(1) time evaluation.
- O(1) space.
- Fast construction (find suitable prime).

• Lemma. Let p be a prime. For any  $a \in \{1, ..., p-1\}$  there exists a unique inverse  $a^{-1}$  such that  $a^{-1} \cdot a \equiv 1 \mod p$ . ( $Z_p$  is a field)

• Example. p = 7

а	1	2	3	4	5	6
a <sup>-1</sup>						

а	1	2	3	4	5	6
a <sup>-1</sup>	1	4	5	2	3	6

- Goal. For random  $a=(a_1a_2...a_r)_p$ , show that if  $x=(x_1x_2...x_r)_p\neq y=(y_1y_2...y_r)_p$  then  $Pr[h_a(x)=h_a(y)]\leq 1/N$
- $(x_1x_2...x_r)_p \neq y = (y_1y_2...y_r)_p \Longrightarrow x_i \neq y_i$  for some i. Assume wlog. that  $x_r \neq y_r$ .

$$\Pr[h_a((x_1 \dots x_r)_p) = h_a((y_1 \dots y_r)_p)]$$

$$= \Pr[a_1x_1 + \dots + a_rx_r \equiv a_1y_1 + \dots + a_ry_r \mod p]$$

$$= \Pr[a_rx_r - a_ry_r \equiv a_1y_1 - a_1x_1 + \dots + a_{r-1}y_{r-1} - a_{r-1}x_{r-1} \mod p] \text{ existence of inverses}$$

$$= \Pr[a_r(x_r - y_r) \equiv a_1(y_1 - x_1) + \dots + a_{r-1}(y_{r-1} - x_{r-1}) \mod p]$$

$$= \Pr[a_r(x_r - y_r)(x_r - y_r)^{-1} \equiv (a_1(y_1 - x_1) + \dots + a_{r-1}(y_{r-1} - x_{r-1}))(x_r - y_r)^{-1} \mod p]$$

$$= \Pr[a_r \equiv (a_1(y_1 - x_1) + \dots + a_{r-1}(y_{r-1} - x_{r-1}))(x_r - y_r)^{-1} \mod p] = \frac{1}{p} \leq \frac{1}{N}$$

p choices for a<sub>r</sub>, exactly one causes a collision by uniqueness of inverses.

- Lemma. H is universal with O(1) time evaluation and O(1) space.
- Theorem. We can solve the dictionary problem (without special assumptions) in:
  - O(N) space.
  - O(1) expected time per operation (lookup, insert, delete).

#### Other Universal Families

• For prime p > 0,  $a \in \{1, ..., p-1\}$ ,  $b \in \{0, ..., p-1\}$ 

$$h_{a,b}(x) = (ax + b \bmod p) \bmod N$$
$$H = \{h_{a,b} \mid a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\}\}$$

Hash function from k-bit numbers to l-bit numbers. a is an odd k-bit integer.

I most significant bits of the k least significant bits of ax

$$h_a(x) = (ax \bmod 2^k) \gg (k-l)$$

$$H = \{h_a \mid a \text{ is an odd integer in } \{1, \dots, 2^k - 1\}\}$$

# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing

- Static dictionary problem. Given a set S ⊆ U = {0,..,u-1} of size N for preprocessing support the following operation
  - lookup(x): return true if  $x \in S$  and false otherwise.
- As the dictionary problem with no updates (insert and deletes).
- Set given in advance.

- Dynamic solution. Use chained hashing with a universal hash function as before ⇒ solution with O(N) space and O(1) expected time per lookup.
  - Can we do better?
- Perfect Hashing. A perfect hash function for S is a collision-free hash function on S.
  - Perfect hash function in O(N) space and O(1) evaluation time ⇒ solution with O(N) space and O(1) worst-case lookup time. (Why?)
  - Do perfect hash functions with O(N) space and O(1) evaluation time exist for any set S?

- Goal. Perfect hashing in linear space and constant worst-case time.
- Solution in 3 steps.
  - Solution 1. Collision-free but with too much space.
  - Solution 2. Many collisions but linear space.
  - Solution 3: FKS scheme [Fredman, Komlós, Szemerédi 1984]. Two-level solution.
     Combines solution 1 and 2.
    - At level 1 use solution with lots of collisions and linear space.
    - Resolve collisions at level 1 with collision-free solution at level 2.
    - lookup(x): look-up in level 1 to find the correct level 2 dictionary. Lookup in level 2 dictionary.

- Solution 1. Collision-free but with too much space.
- Use a universal hash function to map into an array of size N<sup>2</sup>. What is the expected total number of collisions in the array?

$$\begin{split} E[\#\text{collisions}] &= E\left[\sum_{x,y \in S, x \neq y} \begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases} \right] \\ &= \sum_{x,y \in S, x \neq y} E\left[\begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases} \right] \\ &= \sum_{x,y \in S, x \neq y} \Pr[h(x) = h(y)] = \binom{N}{2} \frac{1}{N^2} \leq \frac{N^2}{2} \cdot \frac{1}{N^2} = 1/2 \\ & \text{#distinct pairs} \end{split}$$

- With probability 1/2 we get perfect hashing function. If not perfect try again.
- $\Rightarrow$  Expected number of trials before we get a perfect hash function is O(1).
- $\Rightarrow$  For a static set S we can support lookups in O(1) worst-case time using O(N<sup>2</sup>) space.

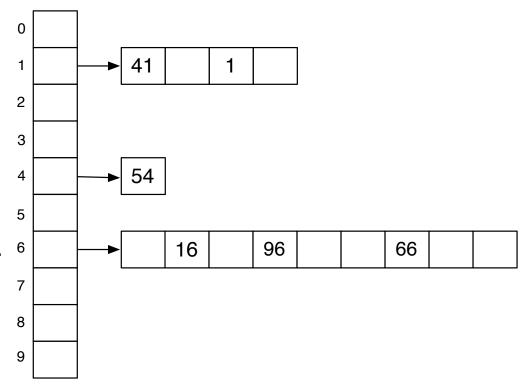

- Solution 2. Many collisions but linear space.
- As solution 1 but with array of size N. What is the expected total number of collisions in the array?

$$E[\#\text{collisions}] = E\left[\sum_{x,y \in S, x \neq y} \begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases}\right]$$

$$= \sum_{x,y \in S, x \neq y} E\left[\begin{cases} 1 & \text{if } h(y) = h(x) \\ 0 & \text{if } h(y) \neq h(x) \end{cases}\right]$$

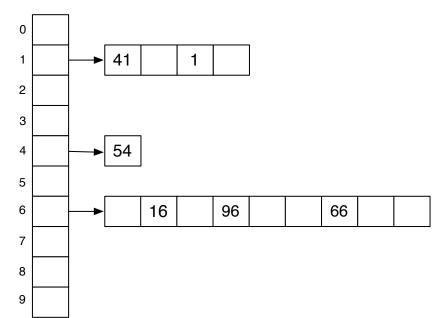

$$= \sum_{x,y \in S, x \neq y} \Pr[h(x) = h(y)] = \binom{N}{2} \frac{1}{N} \leq \frac{N^2}{2} \cdot \frac{1}{N} = 1/2N$$

- Solution 3. Two-level solution.
  - At level 1 use solution with lots of collisions and linear space.
  - Resolve each collisions at level 1 with collision-free solution at level 2.
  - lookup(x): look-up in level 1 to find the correct level 2 dictionary. Lookup in level 2 dictionary.
- Example.
  - S = {1, 16, 41, 54, 66, 96}
  - Level 1 collision sets:
    - $S_1 = \{1, 41\},\$
    - $S_4 = \{54\},$
    - $S_6 = \{16, 66, 96\}$
  - Level 2 hash info stored with subtable.
    - (size of table, multiplier a, prime p)
- Time. O(1)
- Space?

Space. What is the total size of level 1 and level 2 hash tables?

space = 
$$O\left(N + \sum_{i \in \{0,...,N-1\}} |S_i|^2\right)$$
  
#collisions =  $O(N)$   
#collisions =  $\sum_{i \in \{0,...,N-1\}} {|S_i| \choose 2}$ 

space = 
$$O\left(N + \sum_{i} |S_{i}|^{2}\right) = O\left(N + \sum_{i} \left(|S_{i}| + 2\binom{|S_{i}|}{2}\right)\right)$$
  
=  $O\left(N + \sum_{i} |S_{i}|^{2}\right) = O\left(N + \sum_{i} \left(|S_{i}| + 2\binom{|S_{i}|}{2}\right)\right)$ 

- FKS scheme.
  - O(N) space and O(N) expected preprocessing time.
  - Lookups with two evaluations of a universal hash function.
- Theorem. We can solve the static dictionary problem for a set S of size N in:
  - O(N) space and O(N) expected preprocessing time.
  - O(1) worst-case time per lookup.
- Multilevel data structures.
  - FKS is example of multilevel data structure technique. Combine different solutions for same problem to get an improved solution.

# Hashing

- Dictionaries
- Chained Hashing
- Universal Hashing
- Static Dictionaries and Perfect Hashing
