

# Range Minimum Queries and Lowest Common Ancestor

---

Inge Li Gørtz

# Range Minimum Queries and Lowest Common Ancestor

---

- Range Minimum Queries (RMQ) and Lowest Common Ancestor (LCA)
- RMQ
  - Simple solutions
  - Better solution
  - 2-level solution
- Reduction between RMQ and LCA

# Range Minimum Queries

---

- **Range minimum query problem.** Preprocess array  $A[1 \dots n]$  of integers to support
  - $RMQ(i,j)$ : return the (entry of) minimum element in  $A[i \dots j]$ .

1	2	3	4	5	6	7	8	9	10
1	7	12	8	2	5	1	4	8	3

- $RMQ(3,6) = 2$  (index 5)
- Basic (extreme) solutions
  - **Linear search:**
    - Space:  $O(n)$ . Only keep array (no extra space)
    - Time:  $O(j-i) = O(n)$
  - **Save all possible answers:** Precompute and save all answers in a table.
    - Space:  $O(n^2)$  pairs  $\Rightarrow O(n^2)$  space
    - Time:  $O(1)$

# Lowest Common Ancestor

---

- **Lowest common ancestor problem.** Preprocess rooted tree  $T$  with  $n$  nodes to support
  - $LCA(u,v)$ : return the lowest common ancestor of  $u$  and  $v$ .

## Lowest Common Ancestor

---

- Basic (extreme) solutions
  - **Linear search:** Follow paths to root and mark when you visit a node.
    - Space:  $O(n)$ . Only keep tree (no extra space)
    - Time:  $O(\text{depth of tree}) = O(n)$
  - **Save all possible answers:** Precompute and save all answers in a table.
    - Space:  $O(n^2)$  pairs  $\Rightarrow O(n^2)$  space
    - Time:  $O(1)$

## RMQ and LCA

---

- **Outline.**
  - Can solve both RMQ and LCA in linear space and constant time.
    - First solution to RMQ
    - Solution to a special case of RMQ.
    - See that RMQ and LCA are equivalent (can reduce one to the other both ways).

## RMQ

---

## RMQ: Sparse table solution

---

- Save the result for all intervals of length a power of 2.

## RMQ: Sparse table solution

- For all positions we have all power of 2 length intervals starting at that position.

- Space:  $O(n \log n)$

## RMQ: Sparse table solution

- Query:

- Any interval the union of two power of 2 intervals.
- Query the two intervals and take minimum
- Time:  $O(1)$

## RMQ: Linear space

- Consider  $\pm 1$ RMQ: consecutive entries differ by at most 1.

1	2	3	4	5	6	7	8	9	10	11	12	13
4	5	6	5	4	3	2	3	2	3	4	5	4

- 2-level solution: Combine
  - $O(n \log n)$  space,  $O(1)$  time
  - $O(n^2)$  space,  $O(1)$  time.

↓

  - $O(n)$  space,  $O(1)$  time.

## $\pm 1$ RMQ

- Divide A into blocks of size  $\frac{1}{2} \log n$

## ±1RMQ

- Divide A into blocks of size  $\frac{1}{2} \log n$

- 2-level data structure:
  - Sparse table on blocks
  - Tabulation inside blocks.
- RMQ(x,y) = min{ RMQ on blocks i to j, RMQ inside block i-1, RMQ inside block j+1 }.

## ±1RMQ: Data structure on blocks

- Two new arrays.
  - Array A': minimum from each block
  - B: position in A where A'[i] occurs.
- Sparse table data structure on A'.
- Space:  $O(|A'| \log |A'|) = O(n)$ .
- Time:  $O(1)$

## ±1RMQ: Data structure inside blocks

- Precompute and save all answers for each block.
- Gives solution using
  - Space:  $O(n)$  + space for precomputed tables.
  - Time:  $O(1) + O(1) + O(1) = O(1)$ .

## ±1RMQ: Storing the tables

- Naively:  $\log^2 n$  for each table  $\Rightarrow n \log n$  space. 😊
- Observation: If  $X[i] = Y[i] + c$  then all RMQ answers are the same for X and Y.
  - $X = [7, 6, 5, 6, 5, 4]$
  - $Y = [3, 2, 1, 2, 1, 0]$
- Normalize blocks:
  - $X = [0, -1, -2, -1, -2, -3] = Y$
- Normalized block described by sequence of +1s and -1s:
  - $X = Y = [-1, -1, +1, -1, -1]$ .
- How many different normalized blocks are there?
  - length of sequence =  $\frac{1}{2} \log n - 1$
  - #sequences =  $2^{\frac{1}{2} \log n - 1} \leq \sqrt{n}$ .

## ±1RMQ: Data structure inside blocks

- Precompute and save all answers for each normalized block.
- Size of a table:  $O(\log^2 n)$
- For each block save which precomputed table it uses.

- Space:  $O(\sqrt{n} \cdot \log^2 n) + O(n/\log n) = O(n)$
- Plugging into 2-level solution:
  - Space:  $O(n)$  + space for precomputed tables =  $O(n)$ .

## LCA and RMQ

## RMQ and LCA

- We will show

If there is a solution to LCA using  $s(n)$  space and  $t(n)$  time, then there is a solution to RMQ using  $O(s(n))$  space and  $O(t(n))$  time.

If there is a solution to ±1RMQ using  $s(n)$  space and  $t(n)$  time, then there is a solution to LCA using  $O(s(n))$  space and  $O(t(n))$  time.

## RMQ to LCA

1	2	3	4	5	6	7	8	9	10
1	7	12	8	2	5	1	4	8	3

- Cartesian tree.

## RMQ to LCA

1	2	3	4	5	6	7	8	9	10
1	7	12	8	2	5	1	4	8	3

- Cartesian tree.

- $RMQ(3,6) = LCA(3,6)$

## LCA to $\pm 1$ RMQ

- $E = [1, 2, 3, 2, 4, 5, 6, 5, 7, 5, 4, 2, 8, 2, 1, 9, 1]$
- $A = [0, 1, 2, 1, 2, 3, 4, 3, 4, 3, 2, 1, 2, 1, 0, 1, 0]$
- $R = [1, 2, 3, 5, 6, 7, 9, 13, 16]$

- **E: Euler tour representation:** preorder walk, write node preorder number of node when met.
- **A:** depth of node node in  $E[i]$ .
- **R:** first occurrence in  $E$  of node with preorder number  $i$
- $LCA(i, j) = E[RMQ(R[i], R[j])]$ .

## LCA to $\pm 1$ RMQ

- $E = [1, 2, 3, 2, 4, 5, 6, 5, 7, 5, 4, 2, 8, 2, 1, 9, 1]$
- $A = [0, 1, 2, 1, 2, 3, 4, 3, 4, 3, 2, 1, 2, 1, 0, 1, 0]$
- $R = [1, 2, 3, 5, 6, 7, 9, 13, 16]$
- $LCA(5,8) = RMQ(6, 13)$ .

- **E: Euler tour representation:** preorder walk, write node preorder number of node when met.
- **A:** depth of node node in  $E[i]$ .
- **R:** first occurrence in  $E$  of node with preorder number  $i$
- $LCA(i, j) = E[RMQ(R[i], R[j])]$ .

## RMQ and LCA

- **Theorem.** RMQ and LCA can be solved in  $O(n)$  space and  $O(1)$  query time.
