Graph Cuts for Markov Random Fields (MRF)

Henrik Aanæs

January 28, 2011

The aim of this exercise is to give you an introductory practical experience with using graph cuts for solving MRF problems in image analysis. The exercise is to be run from MatLab, (with the use of some supplied C++ functions, linked to via mex)

1 Demo and setup

In order to solve the graph cut problems, a wrapper for the C++ functions found at:
`http://www.adastral.ucl.ac.uk/~ vladkolm/software.html`
have been supplied.[1] In order to compile and get used to this a short M-file is supplied, i.e. `GraphCutDemo.m`.
Tasks:

1. Run `GraphCutDemo.m`. If there is problems compiling please contact a/your TA.
2. Make a drawing of the graph it is running on.
3. Convince yourself that the obtained result is the correct one.

2 Binary Segmentation

Here you should segment an image of a human brain 'slice', which is available in the file `brain.mat`. You should segment it into two classes, fluid and brain matter (In a later exercise brain matter is split into two categories).

Convince yourself that you understand how the prior is derived from a simple clique potential, i.e. make sure you understand how Li's equation (2.45) follows from (2.44).

[1] Please note the copy right notice

	CSF(fluid)	Grey Matter	White Matter
Mean ($\mu(K)$)	32	47	55
Standard deviation ($\sqrt{\Sigma}_K$).	5	4	3

Table 1: Pixel distributions for the image classes.

The label of site (i, j) is denoted f_{ij} and the associated observed pixel value is denoted y_{ij}. The posterior probability is given by

$$P(f_{ij} = K | f_{kl} \in \mathcal{N}_{ij}, y_{ij}) = c(T) \exp\left(\frac{-U(y_{ij}|f_{ij} = K) + \beta n_{ij}(K)}{T} \right) \quad . \qquad (1)$$

Where $U(y_{ij}|f_{ij} = K)$ is derived from the Mahalnanobis distance, and is given by:

$$U(y_{ij}|f_{ij} = K) = \frac{\log(\det(\Sigma_K)) + (y_{ij} - \mu(K))^T \, \Sigma_K^{-1} \, (y_{ij} - \mu(K))}{2} \quad . \qquad (2)$$

You don't need to compute $c(T)$, since it is the same for all class labels K. Notice that the classes have different determinants. The values for the distributions are given in Table 1. For now you should only use the classes 'CSF fluid' and 'Gray Matter'.

Tasks:

1. Write up (2) for the two classes.
2. Compute a segmentation, via graph cuts, based only on one-cliques, i.e. $n_{ij}(K)$ is set to zero or omitted. Thus you should only supply terminal edges to the graph. Comment on the result.
3. Incorporate neighborhood two clique terms i.e. use the $n_{ij}(K)$. Comment on the result, when varying the strength of the neighborhood cost, $n(k)$, (a good starting value is 1).
